Task 1 — Language Translation Tool

A Flask web application where a user enters text, chooses source and target languages, sends the request to a translation service, and sees the translated result. It also includes a copy-result button.

Setup (Windows PowerShell)

```
python -m venv .venv
.venv\Scripts\Activate.ps1
python -m pip install --upgrade pip
pip install -r requirements.txt
python app.py
```

Open `http://127.0.0.1:5000` in your browser.

How it works

- Flask serves the HTML interface and `/api/translate` JSON endpoint.
- `deep-translator` calls GoogleTranslator for translation.
- Source language can be auto-detected; target language must be selected.
- Translation needs internet and the third-party service may change availability or rate limits. Do not send confidential text to external translation services.

Example API request

```
curl -X POST http://127.0.0.1:5000/api/translate -H "Content-Type: application/json" -d "{"text":"Hello world","source
```

Notes

This is a student project and uses an unofficial third-party translation wrapper rather than an authenticated enterprise API. For production, use an officially supported provider API and store credentials in environment variables.
